(54) Title: **BIOMETRIC SYSTEM FOR BIOMETRIC INPUT, COMPARISON, AUTHENTICATION AND ACCESS CONTROL AND METHOD THEREFOR**

## (57) Abstract

A circuit board (140) comprises a microcontroller (150) interfaced with a CCD controller (152), a ROM (154), a RAM (156), and an A/D converter (158) which digitizes the output from the CCD sensor. The CCD controller effects scanning of the CCD sensor to transfer sensed levels of the pixels of a CCD sensor (102). The microcontroller controls the intensity of light produced by an LED (89). An interface controller (160) is interfaced with the microcontroller to effect communication with a serial port of a computer. The microcontroller receives mouse input from the left and right mouse buttons and the X and Y sensors of a mouse and transmits the mouse input to the computer to effect combined functions of thumb print scanning and mouse control.

DescriptionBIOMETRIC SYSTEM FOR BIOMETRIC INPUT, COMPARISON,  
AUTHENTICATION AND ACCESS CONTROL AND METHOD THEREFOR

5

BACKGROUND OF THE INVENTIONClaim of Priority

The present is a Continuation-in-Part of U.S. Patent Application Serial No. 09/312,002, filed on May 14, 1999, for a  
10 Biometric System for Biometric Input, Comparison, Authentication and Access control and Method therefor, the contents of which are incorporated herein by reference.

Field of the Invention

15 The present invention relates to a system for biometric input, comparison, and authentication and, more particularly, to a system and method for securing one or more files, including data files and applications, by restricting available access thereto to authorized individuals through the use of a biometric input  
20 device. The biometric input device provides a compact, yet highly functional configuration and an associated biometric data comparison system provides for controlled access to a computing system based upon comparison of inputted biometric data with biometric data stored in a database.

25

Description of the Related Art

Biometric input devices are known for use with computing systems. Such biometric input devices include computer mouse designs. Existing designs for such biometric input devices have  
30 scanning windows lacking efficient positioning structure for scanning positioning and protection from ambient light, and do not provide mechanical integration of a position sensing ball assembly with an optical scanning assembly maximizing reliability of position sensing ball operation.

35 Biometric data comparison methods and systems are known. Such known systems and methods suffer from various drawbacks including intensive computing power requirements, intensive memory

requirements, slow data transfer, slow comparison, and comparison reliability reduction due to environmental and physiological factors. Known systems also fail to provide for secure communication of biometric data over public lines.

5        Additionally, traditional, commercially available file securing systems are often minimally secure, and if enhanced to the point of providing effective security, are rather difficult and/or complex to utilize, requiring a series of complex steps be performed, and/or requiring the secure maintenance of a password.

10        Naturally, password security systems are not optimally secure unless very elaborate and/or require very long passwords. Accordingly, there is a need for a system which can be convenient and easy to use, but which also provides a substantial amount of security to the files to be secured.

#### 15        Summary of the Invention

          Accordingly, it is an object of the invention to provide a system and method for biometric input and comparison which overcomes the drawbacks of the prior art.

20        It is a further object of the invention to provide an ergonomically advantageous biometric input device which ensures increased precision in sampling biometric data.

          It is still a further object of the invention to provide a biometric data comparison method which controls access to  
25        computers or data networks.

          It is yet another object of the invention to provide a fingerprint comparison method which provides for accurate and rapid comparison of fingerprints while compensating for environmental and physiological factors.

30        An object of the present invention is also to provide a biometric based access control system for use on computers which permits a user to graphically apply biometric access control features to data and applications by the use of a user manipulated biometric protection icon.

35        Briefly stated, the present invention provides a biometric input device, system and method which includes a biometric input

device having a scanning window surrounded by a ridge for ensuring positive positioning of a biometric sample such as a thumb. The biometric input device includes an optical assembly having a prism with a focusing lens disposed on a side thereof and optionally  
5 integrally formed therewith. A biometric comparison method is provided for comparing data from said biometric input device with data from a database using both directional image comparison and clusterized minutia location and direction comparison. A further system is provided for allowing access to computer functions base  
10 on the outcome of the comparison method.

The present invention also provides a biometric input device for accepting a fingerprint of a finger tip having opposing tip sides and a tip end, comprising a device body having a body wall defining an aperture and an optical assembly for scanning the  
15 fingerprint disposed in the device body. The optical assembly has a scanning surface at the aperture upon which the finger tip is placed for scanning of the fingerprint by the optical assembly. A ridge surrounds a portion of a periphery of the aperture such that the ridge engages the opposing tip sides and tip end such as  
20 to position the fingerprint on the scanning surface and block ambient light.

A further feature of the present invention includes the aforesaid biometric input device having a device body with a bottom surface opposing a substrate upon which the device body is  
25 placed, a device body length and a front portion, a middle portion and a heel portion. A movement detection device for detecting movement of the device body relative the substrate is provided and the bottom surface defined a bottom surface aperture through which the movement detection device detects movement of the device body  
30 relative the substrate. The bottom surface aperture is disposed in the heel portion of the device body and the optical assembly is disposed in the middle portion of the device body. In an embodiment of the present invention the movement detection device has a ball protruding through the bottom surface aperture for  
35 engaging the substrate to register the movement of the device body relative the substrate.

According to a feature of the invention, there is further provided a biometric input device for accepting a fingerprint of a finger tip having opposing tip sides and a tip end, comprising a device body having a body side wall defining an aperture, and an optical assembly for scanning the fingerprint disposed in the device body. The optical assembly includes an imaging component for converting a light image into pixel output and a lens for focusing the light image into the imaging component. The optical assembly includes a prism with first, second and third sides and a top side wherein the first side forms a scanning surface at the aperture upon which the finger tip is placed for scanning of the fingerprint by the optical assembly, the second side has the lens for focusing the light image into the imaging component disposed thereon, and the third side has a light absorbing layer.

The present invention also includes the above embodiment wherein, in the alternative or in combination with one another, the lens is formed integrally with the prism and a light emitting device is disposed to emit light into the prism from the top side of the prism to illuminate the fingerprint when disposed at the scanning surface.

According to a still further feature of the invention, there is provided a biometric comparison method comprising a series of steps beginning with (a) scanning in a fingerprint and digitizing the scanning signals to produce a matrix of print image data representing pixels. Next the method proceeds with (b) dividing the print image data into cells, each including a number of pixel data for contiguous pixels, and (c) calculating a matrix of directional image data DI using gradient statistics applied to the cells wherein the directional image data DI includes, for each of the cells, a cell position indicator and one of a cell vector indicative of a direction of ridge lines and an unidirectional flag indicative of a nondirectional calculation result. Processing then continues with (d) skeletonizing the print image data, and (e) extracting minutia from the print image data and producing a minutia data set comprised of data triplets for each minutia extracted, including minutia position data and minutia

direction data.

Next, a comparing process is initiated by (f) providing reference fingerprint data from a database wherein the reference fingerprint data includes reference directional image data DI and a reference minutia data set, and (g) performing successive comparisons of the directional image data DI with the reference directional image data DI and determining a directional difference DifDI for each of the successive comparisons wherein for each of the successive comparisons one of the directional image data DI and the reference directional image data DI is positional shifted by adding position shift data. In a next step (h) it is determined for which of the successive comparisons the directional difference DifDI is the least and the position shift data thereof is selected as initial minutia shift data. A next stage of the comparison process proceeds with (i) positional shifting minutia data by applying the initial minutia shift data to one of the minutia data sets and the reference minutia data set to initially positionally shift the minutia position data and the minutia orientation data, then (j) performing successive comparisons of the minutia data set with the reference minutia data set following the positional shifting minutia data and determining matching minutia based on a minutia distance criteria, a number of matching minutia, and a similarity measure indicative of correspondence of the matching minutia for each of the successive comparisons wherein, for each of the successive comparisons, one of the minutia data set and the reference minutia data set is positional shifted within a minutia shift range R by adding minutia position shift data, and finally (k) determining a maximum similarity measure of the similarity measures of the successive comparisons. The comparison method concludes with (l) determining whether the maximum similarity measure is above a similarity threshold and indicating the reference fingerprint data and the fingerprint data are from the same fingerprint when the maximum similarity measure is above the similarity threshold.

The present invention also includes the above method wherein, as an alternative, the calculation of the directional image data

includes (c1) identifying a directional group of cells comprising all cells of the cells that do not have the unidirectional flag associated therewith; and then excluding from the successive comparisons of minutia data sets, one of the minutia data sets and the reference minutia data set located in or positionally aligned with the cells that have the unidirectional flag associated therewith.

The present invention further provides a feature for use in conducting the successive comparisons of minutia comprising dividing the minutia data set into the minutia data set clusters formed on contiguous one the cells and each including a predetermined number of the minutia before conducting the successive comparisons, conducting the successive comparisons for each of the minutia data set clusters and determining for each of the minutia data set clusters a maximum similarity measure, and finally determining the maximum similarity measure as a sum of the maximum similarity measures of each of the minutia data set clusters.

The present invention also provides for the above comparison method excluding from further processing pairs of the minutia located within a minutia exclusion distance of one another and having minutia direction data with a direction exclusion limit of being in opposite directions.

The present invention further provides a feature wherein in the above comparison method the minutia extraction step extracts minutia limited to ends and bifurcations. Still further there is provided a feature wherein the minutia data set excludes data distinguishing ends and bifurcations.

Yet another feature of the present invention is a biometric comparison system comprising a computer processor assembly preferably having a memory including a reference fingerprint data and at least one of file data and application software, a display, an apparatus for representing at least one of the file data and application software as icons on the display, and a biometric input device, preferably as part of a biometric access control assembly for scanning a fingerprint and storing fingerprint data

representing the fingerprint into the memory. A comparison engine is provided for comparing the fingerprint data with the reference fingerprint data and determining a match if a similarity threshold is satisfied. An access control icon generator permits a user to  
5 move an access control icon on the display and an access control means is provided for controlling access to the at least one of file, be it a data file and/or an application, when a user moves the access control icon onto the icon representing the file, and/or visa versa, whereby access to the at least one file is  
10 permitted only if a user scans a fingerprint producing fingerprint data for which the comparison means determines matches the reference fingerprint data and designates the user as authorized user.

The above, and other objects, features and advantages of the  
15 present invention will become apparent from the following description read in conjunction with the accompanying drawings, in which like reference numerals designate the same elements.

#### Brief Description of the Drawings

20 For a fuller understanding of the nature of the present invention, reference should be had to the following detailed description taken in connection with the accompanying drawings in which:

Figure 1a is a block diagram of a system of the present  
25 invention;

Figure 1b is a block diagram of an alternative system of the present invention;

20 Figure 11 is a simplified depiction of a fingerprint image data FP1 divided into clusters; and

Figure 12 is a simplified depiction of the clusters of Figure 11 applied individually shift to print image data FP2.

25 Like reference numerals refer to like parts throughout the several views of the drawings.

#### Detailed Description of the Preferred Embodiment

Referring to Figure 1A, a computer 50 has a keyboard 52 and a biometric input device 54 with a scanning window 56 for  
30 accepting biometric input. The computer 50 may take the form of a personal computer, a dedicated device such as an ATM machine, a dumb terminal, or a computer on the order of a workstation, minicomputer or mainframe. Optionally, the computer 50 is connected to a remote computer 51 via a link 53 which may be a  
35 direct link via phone lines or direct cabling, or via a network such as a LAN, WAN, intranet or Internet. In order to gain access

to use of the computer 50, or remote computer 51, for all or only specified functions, a user must provide a biometric input to the biometric input device 54 via the scanning window 56. Hereinafter the computer 50 will be referred to, however, it is understood  
5 that the remote computer 51 may optionally perform the functions ascribed to the computer 50 with the computer 50 functioning as a terminal. Likewise, reference to gaining access to use of the computer 50 is understood to include the alternative of access to use of the remote computer 51.

10 The computer 50 compares biometric data, representing the biometric input, with stored biometric data and determines if the biometric data corresponds to any stored biometric data held in a data base. If a correspondence exists, the user is given authorization, that is, the user is allowed access to the computer  
15 50 for performance of the specified functions or for use of the computer 50 in general.

The biometric input device 54 is connected to the computer 50 via an input cord 72. Alternatively, depending upon the type of port the biometric input device 54 uses to communicate with the  
20 computer 50, an embodiment of the present invention has a port adaptor connector 57 connecting the input cord 72 to a corresponding port on the computer 50. A still further alternative provides an embodiment of the present invention wherein a stand-alone adaptor unit 58 channels data via the input  
25 cord 72 and a cable 59 to and from the computer 50. Moreover, if desired, an infra red or other remote and/or wireless data communication structure could be provided.

Referring to Figure 1B, an alternative configuration is shown wherein the scanning window 56 and associated structure is  
30 incorporated in either the computer 50 or the keyboard 52. In such instances, the stand-alone biometric input device 54 is omitted and functions thereof are performed by the computer 50 or by circuitry incorporated in the keyboard 52. It is understood that functions discussed herein with respect to the biometric  
35 input device 54 and the computer 50 may optionally be distributed between the biometric input device 54 and the computer 50 as is

practical.

Referring to Figures 2A and 2B, the biometric input device 54 is shown in the form of a computer mouse 60. Alternatively, the biometric input device may take the form of another type of input device such as a track ball, joystick, touch pad or other variety of input device. The computer mouse 60 preferably includes a left button 62, a right button 64, a ball 66, an X direction sensor 68, and a Y direction sensor 70. Various means may be used to effect input from these devices including mechanical, optical or other. For example, optical means may be substituted for the ball 66 to detect mouse movement. The input cord 72 connects to the computer 50 for effecting data transfer. Optionally, the input cord 72 is replaced by wireless means for effecting data transfer which operate using optical or electromagnetic transmission.

The present invention further includes an optical assembly 80. The optical assembly 80 preferably includes a prism 82, a first lens 84, a mirror 86, a CCD assembly 88, and LED's 89. In particular, the prism 82 has first, second and third sides, 90, 92 and 94, respectively. The first side 90 generally defines the surface of the scanning window 56. Moreover, a coating(s) or a transparent plate may optionally be used to protect the first side 90. The second side 92 preferably includes the first lens 84 disposed thereon or formed integrally with the prism 82. Preferably, the prism 82 is molded integrally with the first lens 84 which provides for reducing part count and simplifying the assembly of the biometric input device 54. The third side 94 includes a light absorbing coating 96.

The CCD assembly 88 includes a CCD sensor 102 and a second lens 104 which functions as an object lens. The first and second lenses 84 and 104 preferably function in conjunction with the mirror 86, as shown by light ray tracings, to focus an image at the first surface 90 onto the CCD sensor 102. Various other lens assemblies and configurations may optionally be realized by those of ordinary skill in the art and are considered to be within the scope and spirit of the present invention.

In order to input biometric data, a user holds the computer

mouse 60 with the index, middle or third finger preferably extended to operate the left and right buttons, 62 and 64, and with the thumb contacting the scanning window 56 to permit an image of a thumb print to be focussed onto the CCD sensor 102.

5 The user then operates any of the left and right buttons, 62 or 64, or other input device, to initiate scanning of the thumb print. Alternatively, scanning may be automatically initiated by circuitry in the biometric input device 54 or the computer 50.

The structural configuration of an illustrated embodiment of  
10 the computer mouse 60 is detailed below wherein a front portion 109 of the computer mouse 60 generally refers to an end portion of the computer mouse 60 from where the input cord 72 preferably extends and where the left and right buttons, 62 and 64, are situated, a heel portion 110 which comprises a rear end portion  
15 where a user's palm typically rests, and a middle portion 111 which is an area where the balls of the user's hand typically are situated. The front portion 109, the heel portion 110, and the middle portion 111 are situated to define three sections of a length L of the computer mouse 60 extending from a front end of  
20 the end portion 109 to a rear end of the heel portion 110.

The scanning window 56 is preferably situated generally on a side of the middle portion 111 and preferably has a ridge 120 framing at least three sides of the scanning window 56. The ridge 120 is configured to accept a perimeter of a user's thumb, thereby  
25 defining a scanning position of the user's thumb in the scanning window 56. Furthermore, the ridge 120 serves to shield the scanning window 56 from ambient light during the scanning process and also to protect the scanning window 56 from damage.

The ball 66 is preferably disposed with a center thereof  
30 within the heel portion 110 of the computer mouse 60. Such disposition of the ball 66 provides advantageous situation of the ball 66 under the palm of the user's hand so that pressure from the palm during operation ensures positive contact of the ball 66 with a substrate upon which the computer mouse 60 is used. The  
35 ball 66 is optionally disposed rearward of a mid-position in the computer mouse 60 wherein the mid-position is a middle of the

length L of the computer mouse 60. In conventional configurations the ball 66 is situated either in the middle portion, forward of the mid-position in the computer mouse, or in the front portion. Such a construction is prone to intermittent contact of the ball  
5 with the substrate due to the user applying excessive downward force to the heel portion of the mouse resulting in the front and middle portions rising from the substrate.

A circuit board 140 contains circuitry for effecting scanning operation of the optical assembly 80. As an alternative to the  
10 optical assembly 80, a contact detection assembly may be realized wherein the scanning window 56 takes the form of a silicon contact sensor. In either configuration, a thumb print of the user is represented by data of an array of pixels. The LED's 89 are mounted on the circuit board 140 in a position above a top surface  
15 of the prism 82 to radiate light into the prism 82 for scanning the thumb print. The embodiment shown has two LED's, but it is realized a single LED may be used or alternative light generating devices may be substituted therefor. Furthermore, although the embodiment shown provides the LED's 89 mounted on the circuit  
20 board 140, the LED's 89 may alternatively be mounted on the prism 82 or molded into the prism 82, at the top side, in the same operation wherein the first lens 84 is molded integrally with the prism 82.

Referring to Figures 3A and 3B, perspective depictions of the  
25 computer mouse 60 illustrate the length L of the computer mouse 60, the disposition of the ball 66 and the structure of the ridge 120. The ridge 120 has an outer surface 122 extending outwardly from a side surface 126 of the computer mouse 60 and an inner surface 124 extending from a peak of the ridge structure to the  
30 scanning surface 56. The ridge 120 is raised from the side surface 126 preferably on at least three sides of the scanning window 56, that is, front, top and bottom sides. On a fourth or rear side, a rise of the ridge 120 from the side surface 126 is optionally omitted to permit ease of insertion of the thumb  
35 against the scanning window 56. The location of the ridge 120 on the three sides of the scanning window 56 ensures positive

location of the thumb for scanning purposes to minimize scan to scan variations in positioning of the thumb print thereby facilitating thumb print comparisons. The center of the ball 66 is shown rearward of the mid-position, the middle portion 111 which includes the middle section of the computer mouse 60, and the three quarter length position. The outer surface 122 is concave but may optionally be flat or convex. Likewise, the inner surface 124 is concave but may optionally be flat or convex. Furthermore, the outer surface 122 may be omitted with the inner surface 124 serving alone to position the thumb wherein the inner surface 124 defines a recess in the side surface 126. However, the rising of the outer surface 122 from the side surface 124 provides for the side surface 126 protruding less outwardly from a mouse body centerline CL1 of the computer mouse 60, shown in Figure 2a, thereby providing for a functionally less cumbersome device.

Referring again to Figure 2a, a surface of the scanning window 56 is preferably inclined with respect to the mouse body centerline CL1 to define an acute angle with respect thereto in the range of  $5^{\circ}$  to  $25^{\circ}$ , and preferably in the range of  $10^{\circ}$  to  $20^{\circ}$ . A front edge of the scanning surface 56 is recessed inwardly toward the mouse body centerline CL1 from a position of the side wall 126 relative to the mouse body centerline CL1. Such positioning provides for an ergonomically advantageous positioning of the thumb when the computer mouse 60 is held. In one embodiment of the invention the scanning window 56 has a length of about 30mm and a width of about 18mm.

Referring again to Figure 2b, the scanning window 56 is inclined in the vertical plane with respect to the substrate upon which the computer mouse 60 rests such that a longitudinal center line CL2 of the scanning surface defines an acute angle with respect to the substrate in the range of  $0^{\circ}$  to  $25^{\circ}$ , and preferably in the range of  $5^{\circ}$  to  $15^{\circ}$ . Such positioning provides for a further ergonomically advantageous positioning of the thumb when the computer mouse 60 is held.

The prism 82 is a right angle prism with a forward acute

angle in the range of 40° to 60° and preferably in the range of 45° to 55°. The mirror 86 serves to redirect light to the CCD assembly 88 thereby providing for a compact arrangement of the optical assembly 80. In one embodiment the forward angle is about 50°.

Referring to Figure 4, an embodiment of circuitry provided on board 140 is shown. A microcontroller 150 is preferably interfaced with a CCD controller 152, a ROM 154, a RAM 156, and an A/D converter 158. Output from the CCD sensor 102 is input to the A/D converter 158 where it is digitized. The CCD controller 152 effects scanning of the CCD sensor 102 to transfer sensed levels of the pixels of the CCD sensor 102. The microcontroller 150 further controls the intensity of light produced by the LED 89. An interface controller 160 is interfaced with the microcontroller 150 to effect communication with a serial port of the computer 50. Other interfaces may be employed permitting data communication with the computer 50. Furthermore, the microcontroller 150 may optionally receive mouse input from the left and right mouse buttons, 62 and 64, and the x and y sensors, 68 and 70, and transmit the mouse input to the computer 50 to effect combined functions of thumb print scanning and mouse control.

The microcontroller 150 is optionally in the form of a programmable logic device (PLD). One such device is the FLEX10K from Altera. The microcontroller 150 controls the CCD controller 152, determines a size and position of a frame, records image data of the frame into the RAM 156, and supports communication protocol with the interface controller 160, such as the RS-232 interface, the PS-2 interface, or the USB interface.

The ROM 154 stores program codes for the microcontroller 150 and may be programmed to effect operations over various interfaces. While discrete IC's are shown, it is realized that the functions of the IC's may be integrated in a single IC. The CCD controller 152 effects reading of successive pixels and lines of the CCD sensor 102. A matrix of data from the pixel array of the CCD sensor 102 forms the frame and is stored in the RAM 156. The frame consists of data representative of the thumb print image

and preferably excludes data from pixels not representative of the thumb print image. Thus, the frame represents a subset of data from a complete scanning of the CCD sensor 102. Accordingly, the amount of data to be processed and sent to the computer 50 is optionally reduced from that of an entire scan of the CCD sensor 102.

In an embodiment of the invention, the interface controller 160 may be incorporated into an interface unit 162 for connecting the input cord 72 to the computer to permit operation over various interfaces by substitution of the interface unit 162 having the desired interface controller 160. The interface unit 162 may be in a separate housing connectable to a desired input port, as shown in Figure 1a as the stand-alone adapter unit 58, or a connector housing itself as show in Figure 1a as the port adapter connector 57. Implementation of the interface unit 162 is dictated by the type of port to be interfaced.

A parallel printer port interface (LPT), that is, a PS2 port interface, may be effected using a microcontroller and a PLD, for example, a ZILOG Corp. Z86E02 in conjunction with a FLEX8K PLD from Altera Corp. In such instance the interface connector 162 is a separate housing which is connected to the computer's printer port with a cable and has a connector for the input cord 72 and for a parallel printer cable through which a printer may be interfaced to the computer 50. Power is supplied to the interface connector 162 and the computer mouse 60 via the PS2 port from the computer 50. Data exchange for the computer mouse's 50 usual mouse input, that is, input from the left and right buttons, 62 and 64, and the x and y sensors, 69 and 70, is preferably effected using standard protocol for PS2 mouse interface and the PLD based on output from the microcontroller 150 of the computer mouse 60.

A full speed USB interface at 12 MBaud may be effected using a processor in the interface unit 162, such as an Intel Corp. 930, which has in built USB functions. In such an instance the interface unit 162 is optionally a separate housing in the form of a stand-alone adapter unit 58 which is connected to the computer's USB port with a cable 59, as shown in Figure 1a, and has a

connector for the input cord 72. Power is supplied from the computer 50 for the interface unit 162 and the computer mouse 60 via the USB port.

A serial port interface, that is, a COM port interface, functioning at 115.2 KB may be effected using a processor in the interface unit 162, such as an Atmel AT29C2051, and an RS232 voltage converter. In such an instance the interface unit 162 is optionally incorporated in a connector for connecting the input cord 72 to the computer's 50 serial port. Power is supplied from the computer 50 via a further connector and is processed by the voltage converter to drive the computer mouse 50.

Referring to Figure 5, a flow chart is shown of operation of the computer mouse 60. Operation begins at a start point 200 and proceeds to decision step 205 to determine whether a read print command is received from the computer 50, referred to as "PC" in the flow chart, to read in a thumb print. If a "read print" command is received, the LED 89 is lit to a maximum level in step 210. Next, in step 215, data from the CCD sensor 102 is read. Following reading CCD data, a decision step 220 is executed to determine whether a finger is detected. When a finger is detected operation proceeds to a decision step 225 to determine whether the light level is acceptable, and if it is not the level is adjusted and operation returns to step 215. If the light level is acceptable, operation proceeds to transmission step 230 wherein a message is sent to the computer 50 indicating that print data is to be sent. In another transmission step 235 a line of print data from the CCD sensor 102 is sent to the computer 50.

Operation then proceeds to a decision step 240 wherein it is determined whether the end of the image data has been sent to the computer 50. If transmission of the image data is not complete, a check is made in a status verification step 245 to see whether there is any mouse input, such as data from any of the left button 62, right button 64, X sensor 68, or Y sensor 70 input by the user and, if such data has been input, it is sent to the computer 50 in a transmission step 250. Operation returns to the transmission step 235 wherein a next line of CCD data is sent to the computer

50 after the mouse input is sent to the computer 60 or if no mouse input is detected. If it is determined in the decision step 240 that transmission of image data is complete, operation returns to the beginning of the flow chart below the start step 200.

5 In step 205, if no read print command is received, operation proceeds to a status verification step 255 to see whether any mouse input has been inputted by the user and, if such data has been inputted, it is sent to the computer 50 in transmission step 260.

10 Once a complete set of image, or print data, is sent to the computer 50, the computer 50 then proceeds to process the data. In the present description, image data is also referred to as print data in reference to the input of a thumb print. However, it is realized that other types of biometric input may be used and  
15 that the present invention may optionally used to process such other data. Examples of such other data include a print image of any of the other digits or images of other unique biometric data such as retinal images. Thus, such applications are considered to be within the scope and spirit of the present invention. Indeed,  
20 the entire operation of the present invention can be contained within the mouse itself, with only an authorization and/or restriction command being passed on to the computer itself.

After the thumb print image is scanned in and the image data thereof transferred to the computer 50, the image data is then  
25 processed and added to a database of print image data or used to gain access to use of the computer 50 by comparison to previously stored print image data in the database. Hereinafter, using image data to gain access is referred to as an authorization process while entering print image data into the database is referred to  
30 as a registration process.

Finger print image analysis may effect comparison of images. Alternatively, the present invention further provides an analysis algorithm that effects comparison of special point maps which indicate where special points, also known as minutia, of a  
35 fingerprint are located. The fingerprint analysis algorithm considers a fingerprint not as a determined object but as a

stochastic object. There is a philosophical analogy, like the Laplas's determinism and the stochastic picture of the world. Another analogy is that the first practically significant results in speech recognition appeared as soon as the first stochastic  
5 models of human's speech had appeared. A discussion of standard approaches is found in the paper A real-time matching system for large fingerprint databases, N.K. Ratha, K. Karu, S. Chen, and A.K. Jain, IEEE Trans. on PAMI, Aug. 1996, vol. 18, no. 8, pp. 799-813, which is incorporated herein by reference for its  
10 teaching relating to fingerprint analysis and modeling.

Factors that randomize print image data include elasticity of skin, humidity, level of impurity, skin temperature, individual characteristics of the user's finger-touch, among many other factors. The basic generation of a special points map optionally  
15 includes multiple finger touches of the same finger, that is, a user's thumb print is optionally scanned multiple times. Each image data from each scanning is referred to herein as a "standard." The greater the number standards of a user stored in the database, the higher the reliability of the recognition is.  
20 The shorter the process of studying multiple standards, the less the reliability of recognition is.

Applicants have conducted experiments showing that the reliability of recognition and the quantity of the standards exhibit the following relationship:

25	Quantity of Standards	Reliability
	1	89%
	3	92%
	5	95%
	7	98%
30	12	99.5%
	20	99.9%

The term "reliability," as used above, relates a probability of recognizing a registered user, that is, matching a user's thumb print data with thumb print data in the data base after one touch.

35 Referring to Figure 6, a flow chart of a fingerprint analyzing algorithm of the present invention is shown. The

algorithm is described below wherein the following definitions apply:

VARIABLE	DEFINITION
5 $X_n(i), Y_n(i), A_n(i)$	i-th minutia description wherein $X_n$ is an x coordinate of the i-th minutia, $Y_n$ is an x coordinate of the i-th minutia, and $A_n$ is an angle of the i-th minutia
10	
FP	fingerprint
N	number of minutia of fingerprint after extraction
15	
FPn	n-th fingerprint
MID	mean inter-ridge distance
20	
DI	directional image
$X_{mas}, Y_{max}$	linear sizes of an input image
25	
$F_x, F_y$	linear sizes (numbers of cells) in directional image,
$F_{stepx} - Y_{max}/F_y$	linear sizes of cells onto which the initial image is distributed to get directional image
30	
$F_n(i,j)$	directional image for n-th fingerprint
Pi	discrete upper bound for 180 degrees
35	

divided into cells having a size defined by  $F_x$  and  $F_y$ . Referring to Figure 7, the print image data  $FP$  is divided into cells as shown by a grid superimposed on the print image and a vector normal to the direction of ridge lines in each cell is calculated.

5 These vectors form the directional image data  $DI$ . Thus, an array of directional image data  $F(i,j)$  is generated where  $i$  and  $j$  denote the cell and the value of  $F(i,j)$  is between 0 and  $P_i$  for directional cells or is set to  $UnDir$  for cells wherein a directional gradient cannot be determined such as for isolated  
10 pixels or pixel groups lacking directionality. The directional image data  $DI$  is then subjected to a smoothing process and its quality factor  $Q$  is determined in a smoothing and quality processing step 320. The smoothing process includes first applying a low-pass filter and then a low-cut filter, after which  
15 a directional smoothing along the directions defined for each cell is effected. Scale normalization, low-pass filtering, low-cut filtering directional image calculation and smoothing are processes that are realizable by those of ordinary skill in the art. Accordingly, detailed discussions thereof are omitted.

20 The quality  $Q$  of a print image data  $FP$  is then calculated by determining a ratio of cells that remain substantially unchanged following the smoothing and quality processing step 320 to the total number of cells. This ratio is then squared and multiplied by the area of the print image data  $FP$  divided by the area of the  
25 entire scanned image. Thus, both the quality of the print image data  $FP$  and absence of image data corresponding to a fingerprint are taken into consideration. Quality decision step 325 is then executed to determine whether the quality  $Q$  of the print image  $FP$  is above a given quality threshold. When the quality  $Q$  is below  
30 the given quality threshold, the process returns to the imaging step 300 for input of new data. This is because it is determined that the quality of the fingerprint is insufficient to base matching upon. If the quality is above the given threshold, processing proceeds a binarization step 330.

35 In the binarization step 330, the image data  $FP$  shown in Figure 8(a) is subjected to preliminary binarization using

subtraction of low-pass filtering resulting in the image data FP producing the image shown in Figure 8(b), followed by directional filtering and binarization resulting in the image of Figure 8(c). Processing continues with execution of a skeletonization step 335 wherein the image data FP is subjected to a thinning and skeletonization processing wherein all ridge lines are reduced to a width of one pixel which results in the image shown in Figure 8(d). In this stage visible ridge lines, that are some pixels in width are being changed to lines one pixel in width. The values on the ridge lines are 1 and for all other areas the values are 0. Now the matrix consists of only two values. Detailed discussions of the filtering and skeletonization processes are omitted as such are realizable by those of ordinary skill in the art given the present disclosure.

A minutia extraction step 340 is next executed upon the image data FP that has been skeletonized. Fingerprints are characterized by various minutia which are particular patterns of the ridges. Two basic types of minutia are a bifurcation 400, or branch, shown in Figure 9(a), wherein a ridge line 402 divides into two ridge lines, 403 and 405, and an end 410, shown in Figure 9(b), wherein a ridge line 412 ends. Each minutia is characterized as a vector represented by a minutia data triplet X, Y, and A wherein X and Y represent the location of the minutia and A is an angle of a vector of the directionallization of the minutia as shown in Figures 9(a) and 9(b).

In a preferred embodiment of the present invention, distinction between end minutia 410 and bifurcation minutia 400 is not made. It is found that exclusion of such distinction results in reduction of data, reduced processing needs and time, while still providing acceptable reliability of fingerprint comparison. Alternatively, distinction may be made with associated increase in processing.

The minutia extraction step 340 further proceeds with exclusion of minutia that are too closely located. Referring to Figure 10, two end minutia at  $(x_1, y_1)$  and  $(x_2, y_2)$ , respectively, and represented by vectors  $(p_1, q_1)$  and  $(p_2, q_2)$ , respectively, are

shown. First, determination is made as to whether the two minutia are within a threshold distance. This threshold distance is optionally a distance  $r$  used to determine matching minutia and discussed below, a fixed distance, or another distance based on mean ridge line separation distance. When two minutia are within the given threshold distance, a determination is made whether the angle between the two vectors  $(p_1, q_1)$  and  $(p_2, q_2)$  is within a given threshold of  $180^\circ$  and the angle between  $(p_2, q_2)$  and  $(x_2 - x_1, y_2 - y_1)$  is within a given threshold of  $0$ . If two minutia satisfy the aforesaid criteria they are excluded because they are too close and aligned in a nearly straight line. As a result of the minutia extraction process, the print image FP is now represented by a data set defined as  $FP = \{Q, N, F(i, j), X(k), Y(k), A(k)\}$  wherein  $N$  is the total number of minutia for the fingerprint FP, and  $X(k)$ ,  $Y(k)$  and  $A(k)$  are the data triplet representing the  $k$ -th minutia. The minutia extraction is advantageous in reducing the amount of data to be processed and thereby reducing the processing time and requirements.

Processing next proceeds to a matching process step 345 wherein the print image data FP is compared to image data in the database. FP1 now refers to the image data of the input fingerprint and FP2 refers to print image data of a fingerprint retrieved from the database in database retrieval step 347. Likewise in this description, other variables are appended with 1 or 2 to represent the respective fingerprint.

It is necessary to find the best alignment of the directional images DI1 and DI2 of  $F1(i, j)$  and  $F2(i, j)$ . Data  $F1(fa, fdx, fdy)(i, j)$  is now calculated wherein rotation by angle  $fa$  and shift by distance  $fx$  and  $fy$  is effected in an orthogonal transformation of  $F1(i, j)$ . After the transformation of  $F1$ , a comparison of  $F1(fa, fdx, fdy)(i, j)$  with  $F2(i, j)$  is then made wherein differences in orientations of corresponding cells of the directional images D1 and D2 is calculated as  $DifDI$ .  $DifDI$  is calculated as the sum of all angular differences between corresponding cells. The values of  $fa$ ,  $fdx$ ,  $fdy$  iteratively varied and for each permutation thereof the transformation of  $F1(fa, fdx, fdy)(i, j)$  is made and

compared with  $F2(i,j)$  to find a  $DifDI$  for each set of  $fa$ ,  $fdx$ ,  $fdy$  values. A set of  $fa$ ,  $fdx$ ,  $fdy$  values is then chosen for which  $DifDI$  is minimal. The chosen set of  $fa$ ,  $fdx$ ,  $fdy$  represent the best shifting parameters for shifting the directional image  $D1$  to effect the best matching directional alignment of  $D1$  and  $D2$ . Subsequent alignment of minutia for matching purposes used the chosen set of  $fa$ ,  $fdx$ ,  $fdy$  as a starting point for adjustments. Additionally,  $BI$  is determined as the number of cells  $(i,j)$  of either  $D1$  or  $D2$  that are not  $UnDir$ .

10 A directional difference decision step 350 is next executed wherein the minimal  $DifDI$  for the chosen set of  $fa$ ,  $fdx$   $fdy$  is compared against a threshold  $DifDI_{TH}$  which may be a set threshold or threshold based on  $BI$ . If  $DifDI$  exceeds the threshold  $DifDI_{TH}$ , then it is determined that the correspondence level, or matching level, between the directional images is insufficient to warrant further comparison of  $FP1$  and  $FP2$  and a different fingerprint image data is chosen for  $FP2$  and processing returns to the beginning of the matching process step 345. If  $DifDI$  is less than the threshold, operation proceeds to similarity measure calculation step 355.

20 Next, the chosen set of  $fa$ ,  $fdx$ ,  $fdy$  for orthogonal transformation is applied as  $(dfx*Fstepx, dfy*Fstepy$  and  $fa)$  to the minutia data triplets  $X1(k)$ ,  $Y1(k)$ , and  $A1(k)$  of  $FP1$ , where  $k$  represents a  $k$ -th minutia. The transformed minutia data triplets of print image data  $FP1$  are then grouped into clusters each containing not less than a given number of minutia, preferably seven. Referring to Figure 11(a),  $FP1$  is illustrated as being divided in four clusters  $CS1$ ,  $CS2$ ,  $CS3$ , and  $CS4$ , which each contain the given number of minutia (not shown). Figure 11(a) is a simplified depiction of the process in that the clusters do not necessarily cover square regions of the print image and the number of clusters is not limited to four. The clusters may be thought of a regional groupings of minutia.

30 Referring now to Figure 11(b), for each of the clusters  $CS1$ ,  $CS2$ ,  $CS3$ , and  $CS4$  on a cluster by cluster basis,  $X1(k)$ ,  $Y1(k)$  of the minutia of the given cluster are all iteratively shifted in  $x$

and y directions by values  $dr$ , wherein  $dr$  is varied within a range  $R$ , such that  $\text{abs}(dr) < R$ , and a comparison of the shifted  $X1(k)$ ,  $Y1(k)$ ,  $A1(k)$  is made against all minutia in a BI grouping of FP2 for each set of  $dr$  set values to identify minutia of FP1 matching those of FP2. A pair of minutia are considered matched when a distance between them is less than a threshold  $r$  discussed below. The BI grouping of FP2 is the group of cells in FP2 that are not UnDir. For each shift of a cluster, a similarity measure  $Smt$  is taken, which is the sum of the following term for each set of matched minutia in the cluster:

$$d$$

$$m(x1,y1;x2,y2) = a \int_0^{\delta} \exp(-z/2) dz + \delta,$$

where

$$d = (x1-x2)^2 + (y1-y2)^2$$

and  $a$ ,  $\delta$  and  $0$  are empirical values. In an embodiment of the invention,  $a$  is 150,  $\delta$  is set equal to  $R1$ , where  $R1$  equals 30, and  $R2$ , where  $R2$ , equals 20,  $R1$  and  $R2$  being discussed below, and  $0$  is set equal to 4. These values are exemplary and alterable without departing from the scope and spirit of the present invention. For each cluster, the set of  $dr$  values yielding the greatest similarity measure  $Smt$  is selected and the total sum of the greatest similarity measure of each cluster is taken to find a similarity measure  $Smt(FP1, FP2)$  for the comparison of FP2 to FP2).

As noted above, comparison of fingerprints is often hampered by various environmental and physiological factors. The division of FP1 into clusters provides compensation in part for such factors as stretching and shrinking of the skin. For a given cluster, the total distance difference due to stretching or shrinkage between two minutia is limited due to the limited size of the cluster area. Thus, adverse effects of shrinking and stretching are minimized. Accordingly, individual cluster

shifting and comparison are a preferred embodiment of the present invention. Alternatively, division of FP1 into clusters may be omitted and shifting and comparison of FP1 as a whole effected.

The maximum similarity measure  $Smt(FP1, FP2)$  is generated for the best comparisons of all clusters of FP1 with FP2, along with a number  $Nmat$  of matched minutia, and a number  $Ntot$  which is the total number of minutia within the BI grouping of FP1. An overall similarity measure for the comparison of FP1 with FP2 is calculated as follows:

$$Nmt(R, r, BI, Ntot) = Smt(FP1, FP2) - DifDI$$

where  $Smt(FP1, FP2)$  is a sum of the best  $Smt$  of each cluster. Thus, this takes into account the maximal number of matched minutia,  $DifDI$  and statistical peculiarities of distances distribution.

Processing then proceeds to similarity decision step 360 wherein  $Nmt(R, r, BI, Ntot)$  is compared with a threshold  $Thr(R, r, BI, Ntot)$ . If  $Nmt(R, r, BI, Ntot)$  is greater than the threshold  $Thr(R, r, BI, Ntot)$ , it is determined the FP1 matches FP2 and a match is indicated in match indication step 365. If  $Nmt(R, r, BI, Ntot)$  is less than or equal to the threshold  $Thr(R, r, BI, Ntot)$  it is determined the FP1 does not match FP2 and execution proceeds to the data base retrieval step 347 for the selection of another set of print data from the database for use as FP2 in the process which returns to the matching process step 345. Indication of a match is then used to permit access to the computer 50 in general or specific functions thereof.

In a preferred embodiment of the invention, the threshold  $Thr(R, r, BI, Ntot)$  is determined on the basis of threshold training using a sample pool of fingerprints from a number of individuals. The sample pool is composed of a number of samples, or standards, from each individual in the pool. The number of samples, from each individual in the pool. The number of samples from each individual in one example is 4 and the number of individuals is in a range of 100 to 1000. The number of samples and individuals may be varied from the exemplary values and range without departing from the scope and spirit of the present invention. The process

steps 305 through 355 of Figure 6 are then executed for each print with every print being compared to every other print. Since the sample pool is known, comparisons of prints from a same individual and comparisons of prints from different individuals are known.

5 In performing the threshold training, n number of variations of R and r are used and are shown below as R1, R2 and r1, r2 for an example where n=2. For example, values are set such that  $R1 < R2$  and  $r1 < r2$  where  $R1=2 \cdot \text{MID}$ ,  $r1=\text{MID}$ ,  $R2=3.5-4 \text{ MID}$ , and  $r2=2 \cdot \text{MID}$ . MID is the mean inter-ridge distance of the prints in the sample pool. The following values are found:

$\text{NmtS}(R1, r1, BI, N_{\text{tot}})$ ,  $\text{NmtA}(R1, r1, BI, N_{\text{tot}})$ , and  
 $\text{NmtS}(R2, r2, BI, N_{\text{tot}})$ ,  $\text{NmtA}(R2, r2, BI, N_{\text{tot}})$ ,

where NmtS is number of matched minutia for prints compared from the same individual while NmtA is the number of matching minutia resulting from the comparison of fingerprints from different individuals.

For a given BI,  $N_{\text{tot}}$  (within subrange of appropriate quantization),  $\text{BestA}(n, BI, N_{\text{mat}})$  is set to the max  $\text{NmtA}(Rn, rn, BI, N_{\text{tot}})$ , of all the comparisons of fingerprints from different individuals, and  $\text{MinNmtS}(Rn, rn, BI, N_{\text{tot}})$  is set to the minimum  $\text{NmtS}(Rn, rn, BI, N_{\text{tot}})$  of all comparisons of fingerprints from the same individual for  $n=1, 2$ , etc. The threshold are then calculated as follows:

25  $\text{Thr}(n, BI, N_{\text{mat}}) = (\text{BestA}(n, \dots) = \text{MinNmtS}(Rn, rn, \dots))$ ,  
 where

$$\text{NmtS}(Rn, \dots) > \text{BestA}(Rn, \dots) / 2.$$

In conjunction with the above discussion of threshold calculations, the similarity decision step 360 produces a positive match indication if for the current BI,  $N_{\text{tot}}$ :

$\text{Nmt}(R1, r1, BI, N_{\text{tot}}) > \text{Thr}(1, BI, N_{\text{tot}})$ , or

$\text{Nmt}(R2, r2, BI, N_{\text{tot}}) > \text{Thr}(2, BI, N_{\text{tot}})$ .

If this condition is not found, then the dichotomy analysis gives some correction. The results of identical and not identical matchings is considered as two classes of patterns and the pairs

of values  $Nmt(R1, r1, \dots)$ ,  $Nmt(R2, r2, \dots)$  as feature coordinates. The dichotomies are performed by the second order threshold functions which are calculated according to chapter 2.3. in the classical book by J.Tu and R. Gonzalez "Pattern Recognition Principles" Addison-Wesley Publ. 1974, which is incorporated  
5 herein by reference for its relevant dichotomy teachings.

The complete description to be stored in the database is a multilevel structure of 4 (or more) FP data sets taken from the different applications of the same FP. Each level of the  
10 structure corresponds to minutia appearance frequencies for all FP codes.

Optionally, instead of using thresholds for the similarity comparison as discussed above, fixed values may be chosen and used as threshold values.

15 The data base of fingerprints of individuals for whom identification is required is created by a registration process. The registration process entails a given individual having their fingerprints scanned a number of times, for example four. Of the four scans, the scanning producing the greatest number of minutia  
20 is then selected for the database.

The present invention further includes use of the above fingerprint minutia extraction and comparison process in conjunction with a cryptographic protection process. For this aspect of the invention, the computer 50, also referred to as the  
25 client, will send fingerprint data to the remote computer 51, also referred to as the server, over the link 53 which may be, for example, a link over the Internet. Thus, security protection for data sent over the link 53 is required.

There are three different cryptographic procedures used in  
30 the cryptographic process. As they are not used simultaneously, they are described below separately. All cryptographic parts are written in italic font. The cryptographic method employed is RSA encryption.

#### I. User registration

35 In order to use the cryptographic process, the user must first register his fingerprint with the server. In order to

maintain security, the fingerprint data must be encrypted to prevent unauthorized interception thereof. The following steps are used:

- 5           1. User fills in a registration form including a UserID. Other information such as Name, E-mail address, etc. may be included.
2. User scans his fingerprint into the computer 50 via the biometric input device where it is stored as image data. The image data is typically on the  
10           order of 64 KB.
3. The computer 50 then converts the image data of the finger to the data set defined as  $FP = \{Q, N, F(i,j), X(k), Y(k), A(k)\}$  using processing steps 310 through 340 shown in Figure 6. This data set is also  
15           referred to herein as a passport. Optionally, components of the data set may be omitted, such as  $F(i,j)$ , so the passport may be shortened to about 1.2 KB.
4. The client, computer 50, then sends a request for the public key to the server via the link 53.  
20           5. Server sends its public key  $K_e$  via the link 53.
6. Client encrypts its passport and his UserID using RSA algorithm and public key  $K_e$ . In a preferred embodiment the length of the key is 512 bits:  
25            $C = \text{RSA.Encode Public } (K_e, \text{passport}, \text{UserID})$
7. The computer 50 sends C to the remote computer 51 via the link 53.
8. The remote computer 51 decrypts message using its secret key  $K_d$ :  
30            $M = \text{Passport} + \text{UserID} = \text{RSA.Encode Secret } (K_d, C)$
9. The remote computer 51 then adds the UserID and passport to the database.

## II. User authorization

The user authorization process is used where a user wishes to gain access to the remote computer on the basis of his finger print matching one in the database.

1. User scans his fingerprint image data into the computer 50.
2. The computer converts the image of the finger to the passport using processing steps 310 through 340 shown in Figure 6.
3. The computer 50 sends a request over the link 53 to the remote computer 51, the server, for the public key to the server.
4. The remote computer 51 sends its public key  $K_E$  to the computer 50.
5. The computer 50 encrypts the passport and UserID using RSA algorithm using the public key  $K_E$ :  
 $C = \text{RSA EncodePublic}(K_E, \text{passport}, \text{UserID})$
6. The computer 50 sends C to the remote computer 51 via the link 53.
7. The remote computer 51 decrypts message using its secret key  $K_D$ :  
 $M = \text{passport} + \text{UserID} = \text{RSA EncodeSecret}(K_D, C)$
9. The remote computer 51 then searches the database for the UserID, finds the corresponding passport, and executes steps 345 through 365 of Figure 6 using the passport retrieved from the database as FP2. Optionally, step 350 is omitted. If the comparison of step 360 is positive, access is authorized. If the UserID does not exist or the comparison result of step 360 negative, authorization for access is refused.

III. Installation of the server and addition of new users is effected by the following steps:

- 35           1.    Installation of normal Web-server components.

2. Generation of the public and secret keys for the administrator of the server: first of all random integer is generated, possibly based on administrator's fingerprint, which is part random, then the deterministic algorithm is started to determine public and secret keys.
3. When the new user is being registered, server takes its UserID and passport and encrypts them with administrator's public key.

10

Usage of two different keys makes it more difficult to corrupt fingerprint data since an intruder must obtain both public and private keys to complete his attack. Different servers will have different keys to ensure that corrupted fingerprint data (i.e. stolen from some server) could not be used on other servers.

The 512-bits RSA keys are extremely difficult to crack. In fact, the keys of that length are not known to have been broken, so current cryptography declares them as keys for long-term secret information (30-50 years or longer). Average time of encryption of passport (client side) is less than a second. Average time of decryption of passport (server side) is about 2 seconds, so it is reasonable to predict that network delays would be more significant. Besides, servers are usually more powerful than the client computers.

A further aspect of the present invention provides software for working preferably in the Windows or a Macintosh environment. In particular, a protection icon is preferably provided which an authorized user, one whose biometric passport has produced a positive comparison, may move and drop on a file of data or program object to require that future access thereto be permitted only when a positive fingerprint comparison has been executed. Optionally, the user may input a list of UserID's to be designated as authorized users and for whom access will be allowed.

In particular, the previously described embodiment of the biometric input device wherein comparison is performed utilizing

fingerprint data can be considered part of the biometric access control assembly to be utilized as part of the file securing system and method of the present invention. For example, preferably the file securing system works in conjunction with a computer processor assembly which contains an item to be secured thereon. That item to be secured can include any type of file, including a data file or an application file. (For the purposes of this application, the term file is utilized to designate data and/or a complete application and/or a portion thereof).

Furthermore, operatively associated with the computer processor assembly is a display. Preferably utilizing a specific and/or conventional Windows™ and/or Macintosh type operating system, the computer processor assembly is structured to represent the item to be secured in the form of an icon on the display. This item icon can be readily viewable, such as on a desktop, or may be accessed through a normal browser of the computer processor assembly. Additionally, it is understood that a large plurality of icons representing a large number of items may be contained by the computer processor assembly, however, only one of the possible many items which are desired to be secured will be referenced in the following description in association with an item icon.

The file securing system of the present invention further includes an access control icon, also preferably visible to the user on the computer processor assembly. The access control icon is represented on the display of the computer processor assembly and is at least temperately, but preferably generally always, independent from the item icon that represents the item to be secured. The access control icon, however, is preferably configured to be moved on the display, preferably in a conventional manner such as by selecting the access control icon and holding down one or more buttons on a mouse type pointer. Specifically, the access control icon is structured to be moved and/or dragged at least partially into operative proximity with the item icon representing the item to be secured. Preferably, this operative proximity includes an at least partial overlapping of the access control icon onto the item icon, said positioning of

the access control icon into the operative proximity with the item icon resulting in a restriction of subsequent access to the item to be secured to only an authorized user. Of course, if desired, the item icon can conversely be moved onto the access control icon to achieve a similar access restriction.

Preferably, the file securing system further includes a biometric access control assembly, such as that previously recited. The biometric access control assembly therefore includes a biometric input device that is operatively associated with the computer processor assembly. In this regard the biometric input device can be operatively associated with the computer pointer, such as the mouse, in the manner previously described and/or can be positioned directly in association with the computer processor assembly and/or as a separate distinct article. In any such embodiment, however, the biometric input device is preferably structured to identify a biometric identifier of an accessing user. Although it is recognized that the biometric identifier can include a variety of items, including a retinal image and/or voice pattern, is preferred that the biometric identifier comprise a finger print of the accessing user who wishes to gain access to the item that has been secured by the file securing system.

In identifying the biometric identifier, the biometric access control assembly is further structured to at least partially determined if the accessing user is an authorized user. This authorizing user can either be the restricting user, who originally moved the access control icon onto the item icon, and/or can be a plurality of other authorizing users, either designated based on certain security protocols, and/or specifically designated by the restricting user. In order to identify when the accessing user is an authorized user, the biometric access control assembly of the file securing system also preferably comprises a biometric referenced data storage assembly. The biometric reference data storage assembly is preferably part of the computer processor assembly, however, it is recognized that all or part of the biometric access control assembly can be independent of the computer processor assembly and/or contained

thereby. In particular, the biometric referenced data storage assembly maintains biometric reference data relating to at least one authorized user, but preferably all authorized users, and preferably the referencing user as an authorized user. In this  
5 regard, the biometric access control assembly may be also be configured to automatically make the restricting user an authorized user and/or can first ensure that a restricting user is an authorized user prior to allowing that restricting user to limit the access to the item to be secured. In such a manner,  
10 securement of files can only be achieved by authorized users as well as subsequent access to the file. Accordingly, preferably utilizing the aforementioned comparison and/or matching algorithm and/or further effectively secured matching system, the biometric input device of the biometric access control assembly includes a  
15 finger print scanner.

Preferably utilizing the preceding file securing system, the present invention also provides for a method of securing an item contained on a computer processor assembly. In particular, the method includes the initial steps of representing the item to be  
20 secured as an item icon, such as on the computer processor assembly display, designating an access control icon, also preferably on the computer processor assembly display, selecting the access control icon and moving it into operative proximity with the item icon, and restricting subsequent access to the item  
25 to only authorized users as a result of that movement of the access control icon into operative proximity with the item icon. Additionally, in the preferred embodiment wherein the biometric access control assembly is included, the method further includes the additional steps of storing a quantity of biometric reference  
30 data, such as fingerprint data, corresponding one or more authorized users, and identifying a biometric identifier for an accessing user that wishes to access the item that has been secured. Subsequently, the biometric identifier of the accessing user is compared to the biometric referenced data and it is  
35 determined if it correspond the biometric referenced data of at least one authorize user so as to permit subsequent access to the

item which has been secured.

Having described preferred embodiments of the invention with reference to the accompanying drawings, it is to be understood that the invention is not limited to those precise embodiments, and that various changes and modifications may be effected therein by one skilled in the art without departing from the scope or spirit of the invention as defined in the appended claims.

Now that the invention has been described,

Claims

1. A biometric comparison system comprising:

a computer having a memory including a reference  
fingerprint data and at least one of file data and application  
5 software;

a display;

means for representing at least one of file data and  
application software as icons on said display;

a biometric input device for scanning a fingerprint and  
10 storing fingerprint data representing said fingerprint into said  
memory;

comparison means for comparing said fingerprint data  
with said reference fingerprint data and determining a match if a  
similarity threshold is satisfied;

15 an access control icon generator permitting a user to  
move an access control icon on said display;

access control means for controlling access to said at  
least one of file data and application software when a user moves  
said access control icon onto said icon representing said at least  
20 one of file data and application software whereby access to said  
at least one of file data and application software is permitted  
only if a user scans a fingerprint producing fingerprint data for  
which said comparison means determines matches said reference  
fingerprint data.

25 2. A file securing system comprising:

a computer processor assembly, said computer processor  
assembly including at least one item to be secured thereon;

a display operatively associated with said computer processor  
assembly;

30 said computer processor assembly further structured to  
represent said item to be secured as an icon on said display;

an access control icon represented on said display of said  
computer processor assembly at least temporarily independent from  
said icon representing said item to be secured; and

35 said access control icon structured to be moved on said  
display at least temporarily and at least partially, into

operative proximity with said icon representing said item to be secured, and being structured to result in a restriction of subsequent access to said item to be secured to only an authorized user.

5           3. A file securing system as recited in claim 2 further comprising a biometric access control assembly, said biometric access control assembly comprising a biometric input device operatively associated with said computer processor assembly and structured to identify a biometric identifier of an accessing  
10 user, said biometric access control assembly structured to at least partially determine if said accessing user is one of said authorized users.

          4. A file securing system as recited in claim 3 wherein said biometric access control assembly further comprises a  
15 biometric reference data storage assembly structured to maintain at least biometric reference data relating to at least one authorized user.

          5. A file securing system as recited in claim 4 wherein said computer processor assembly at least partially includes said  
20 biometric reference data storage assembly.

          6. A file securing system as recited in claim 4 wherein said biometric input device at least partially includes said biometric reference data storage assembly.

          7. A file securing system as recited in claim 4 wherein  
25 said biometric access control assembly is structured to compare said biometric identifier of said accessing user identified by said biometric input device to said biometric reference data.

          8. A file securing system as recited in claim 3 wherein said biometric access control assembly is structured to identify  
30 a biometric identifier of a restricting user attempting to move said access control icon into operative proximity with said item to be secured.

          9. A file securing system as recited in claim 8 wherein said biometric access control assembly is structured to designate  
35 said restricting user as one of said authorized users.

          10. A file securing system as recited in claim 8 wherein

said biometric access control assembly is structured to permit said restricting user to designate said authorized users.

11. A file securing system as recited in claim 8 wherein said biometric access control assembly is structured to permit  
5 said restriction of subsequent access to said item to be secured only if said restricting user is identified as one of said authorized users.

12. A file securing system as recited in claim 3 wherein said biometric input device comprises a fingerprint scanner.

10 13. A file securing system as recited in claim 12 wherein said biometric input device is operatively associated with a computer pointer assembly.

14. A file securing system as recited in claim 2 wherein said item to be secured comprises an application.

15 15. A file securing system as recited in claim 2 wherein said item to be secured comprises a data file.

16. A file securing system as recited in claim 2 further comprising a plurality of said authorized users.

17. A method of securing an item contained on a computer  
20 processor assembly comprising the steps of:

representing the item as an item icon;

designating an access control icon;

selecting said access control icon and moving said access control icon into operative proximity with said item icon; and

25 restricting subsequent access to the item to only authorized users as a result of said movement of said access control icon into operative proximity with said item icon.

18. The method securing an item recited in claim 17 further comprising the steps of:

30 storing a quantity of biometric reference data corresponding to said authorized user;

identifying a biometric identifier of an accessing user seeking access to the item;

35 comparing said biometric identifier of said accessing user to said biometric reference data; and

determining if said biometric identifier of said accessing

user corresponds said biometric reference data of at least one of said authorized users.

19. The method securing an item recited in claim 18 wherein said step of identifying said biometric identifier of said  
5 accessing user further comprises scanning a fingerprint of said accessing user.
